Link to this page: If you shun the sun, suffer from milk allergies, or conform them to a strict diet, you may be at risk of vitamin D deficiency. Known as vitamins in sun, vitamin D produced by the body of response to skin have been exposed to sunlight. It also occurs naturally in some foods – including some fish, fish oils, and yolk eggs – and to daily strengthening and producing grains. Vitamin D is essential for strong bones, because it helps the body use calcium in diet. Traditionally, vitamin D deficiency has been associated with bunnies, a disorder in which the bone tissue is not properly mineralized, leading to soft bones and skeletal distortions. But increasingly, research is revealing the importance of vitamin D in protecting against a host of health problems. Symptoms of bone pain and muscle weakness can mean you have a vitamin D deficiency. However, for many people, the symptoms are subtle. But even without symptoms, too little vitamin D can pose health risks. Low blood levels of vitamins were associated with the following: Research suggests that vitamin D could play a role in the prevention and treatment of a number of different conditions, including type 1 with type 2 diabetes, hypertension, glucose intolerance, and multiple sclerosis. Vitamin D deficiency can occur for a number of reasons: You don't consume the recommended levels of vitamin A over time. This is likely if you follow a strict diet, because most of the natural sources are cattle-based, including fish and fish oils, yolk eggs, strengthened milk, and beef. Your exposure to the sunlight is limited. Because the body performs vitamin D when your skin is exposed to sunlight, you can be at risk for deficiencies if you are homebound, live in northern latitude, wear long clothes or top covers for religious reasons, or have an occupation that prevents sun exposure. You have skin. Melanin in pigment reduces the skin capacity to make vitamin D in response to the sun's light exposure. Some studies show that older adult and dark skin are at high risk for vitamin D. Renal deficiencies you cannot convert vitamin D into its active form. As people age, the kidneys are less able to convert vitamin D into its active form, therefore increasing the risk of vitamin D deficiency. Your digestive tract cannot adequately absorb vitamin D. Certain medical problems, including Crohn's disease, cystic fibrosis, and celiac disease, can affect your instinct ability to absorb vitamin D from the food you eat. You obey. Vitamin D is extracted from the blood by fat cells, changing its release in the circulation. People with a mass body index of 30 or older often have low blood levels of vitamin D. The most accurate way to measure how much vitamin D is in your body is the 25-hydroxy vitamin D blood test. A level of 20 nanograms/milliliter's 50 ng/mL is considered adequate for healthy people. A level less 12 ng/mL indicates vitamin D deficiency. Treatment for vitamin D deficiency involves getting more vitamin D – through diet and supplements. Although there is no consensus on vitamin D levels needed for better health – and is likely different depending on age and health conditions – a concentration of less than 20 nanograms per milliliter is generally regarded as inadequately, which requires treatment. Guidelines from the Institute of Medicine increase the range of recommended dietary (RDA) of vitamin D to 600 international units (IU) for everyone aged 1–70, and raised it to 800 IU for adults aged 70 to optimize bone health. The upper limit was also raised to 4,000 IU. Doctors can prescribe more than 4,000 IU to correct a vitamin D deficiency. If you don't spend much time in the sun or always are careful to cover your skin (sun resides vitamin D), you should talk to your doctor about taking a vitamin D supplement, particularly if you have risk factors for vitamin D.
